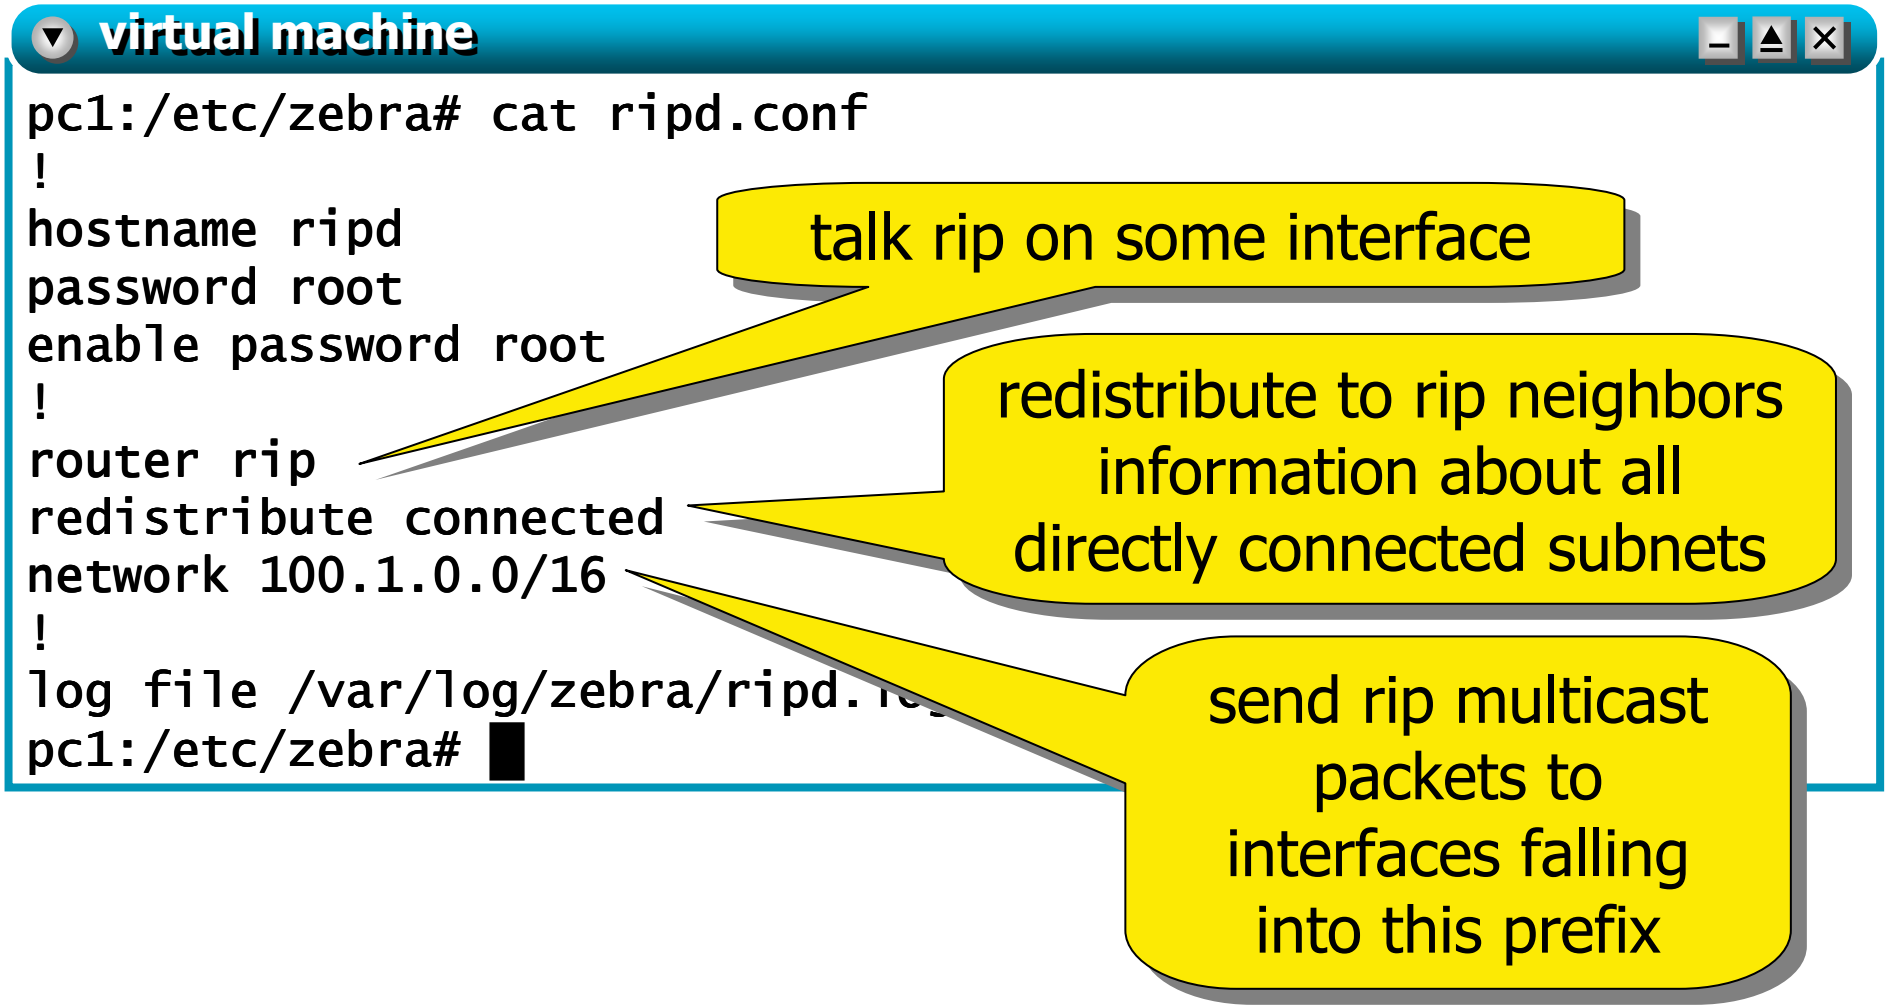
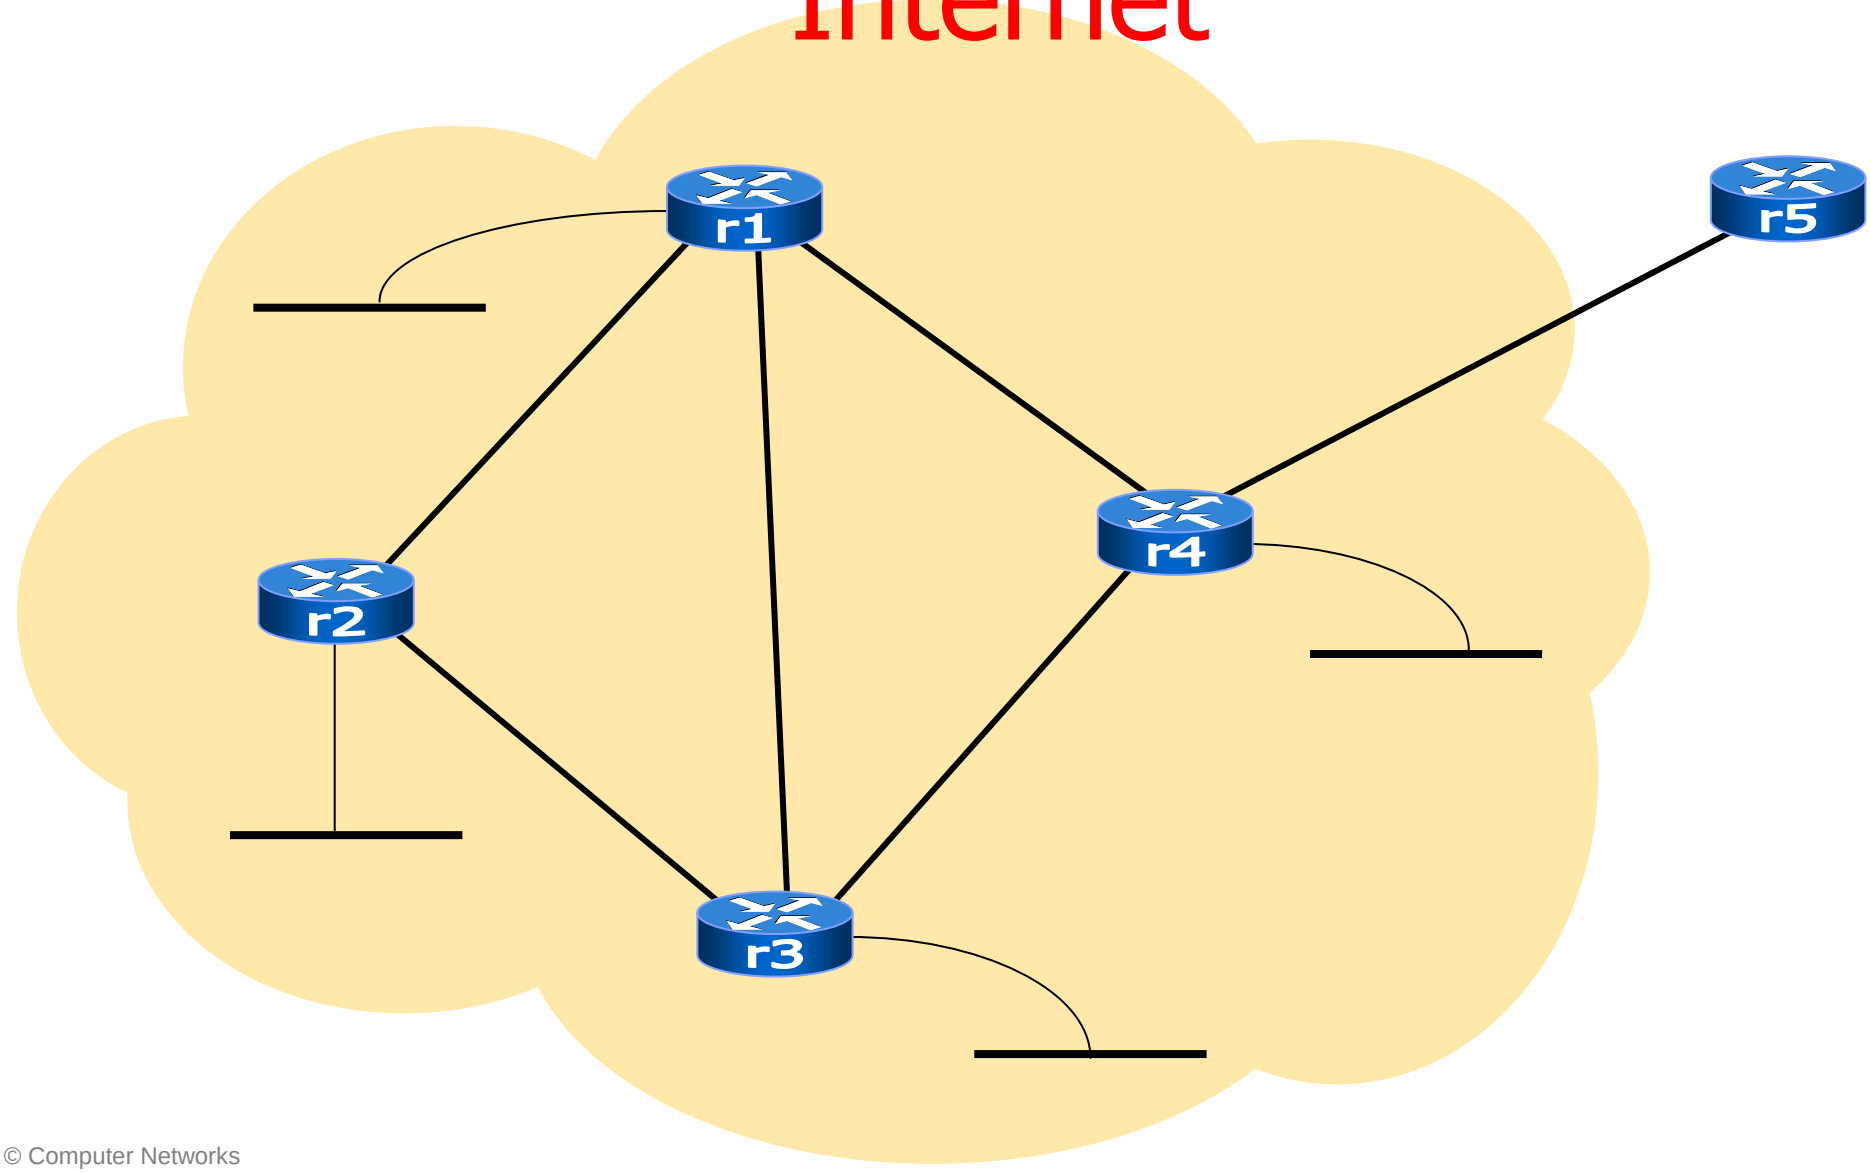
routing protocols

- routing protocols are used to automatically update the routing tables
- they fall into two main cathegories:
  - link-state routing protocols
    - approach: send the minimum information to everyone
    - each router reconstructs the whole network graph and computes a shortest path tree to all destinations
    - examples: is-is, ospf
  - distance-vector routing protocols
    - approach: send all your information to a few
    - update your routing information based on what you hear
    - examples: rip, bgp
- in this lab we will see an example of RIPv2 protocol on zebra boxes

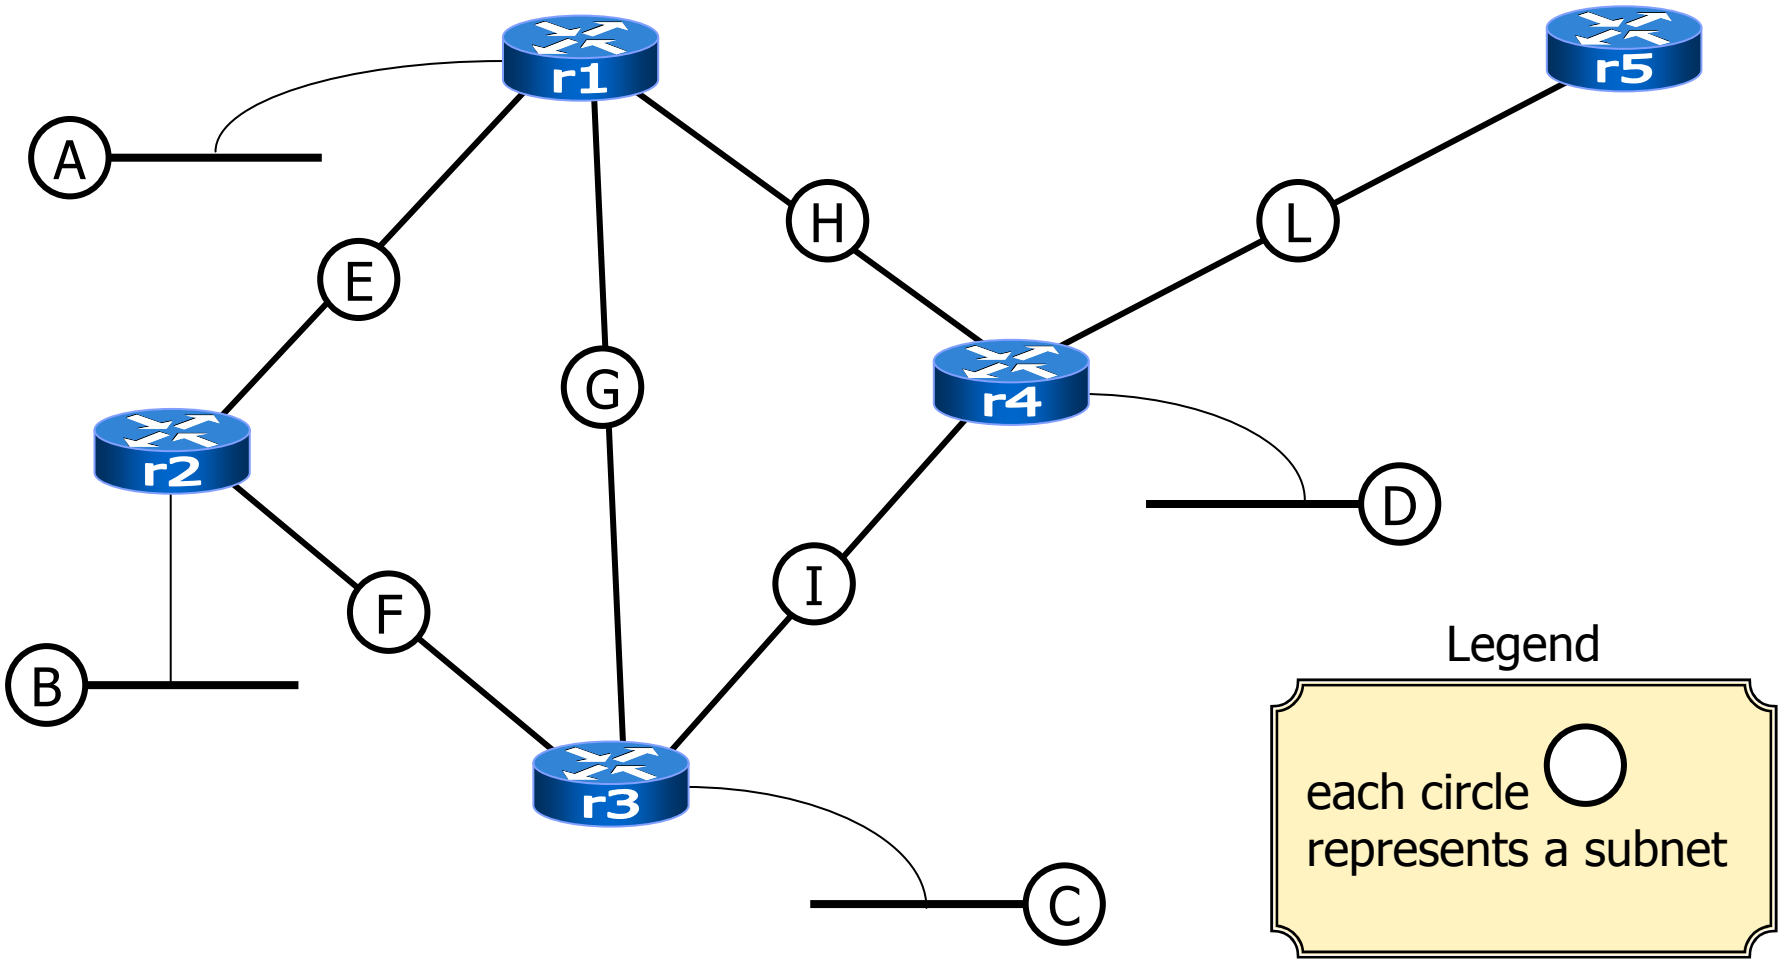
sample ripd configuration file (`ripd.conf`)



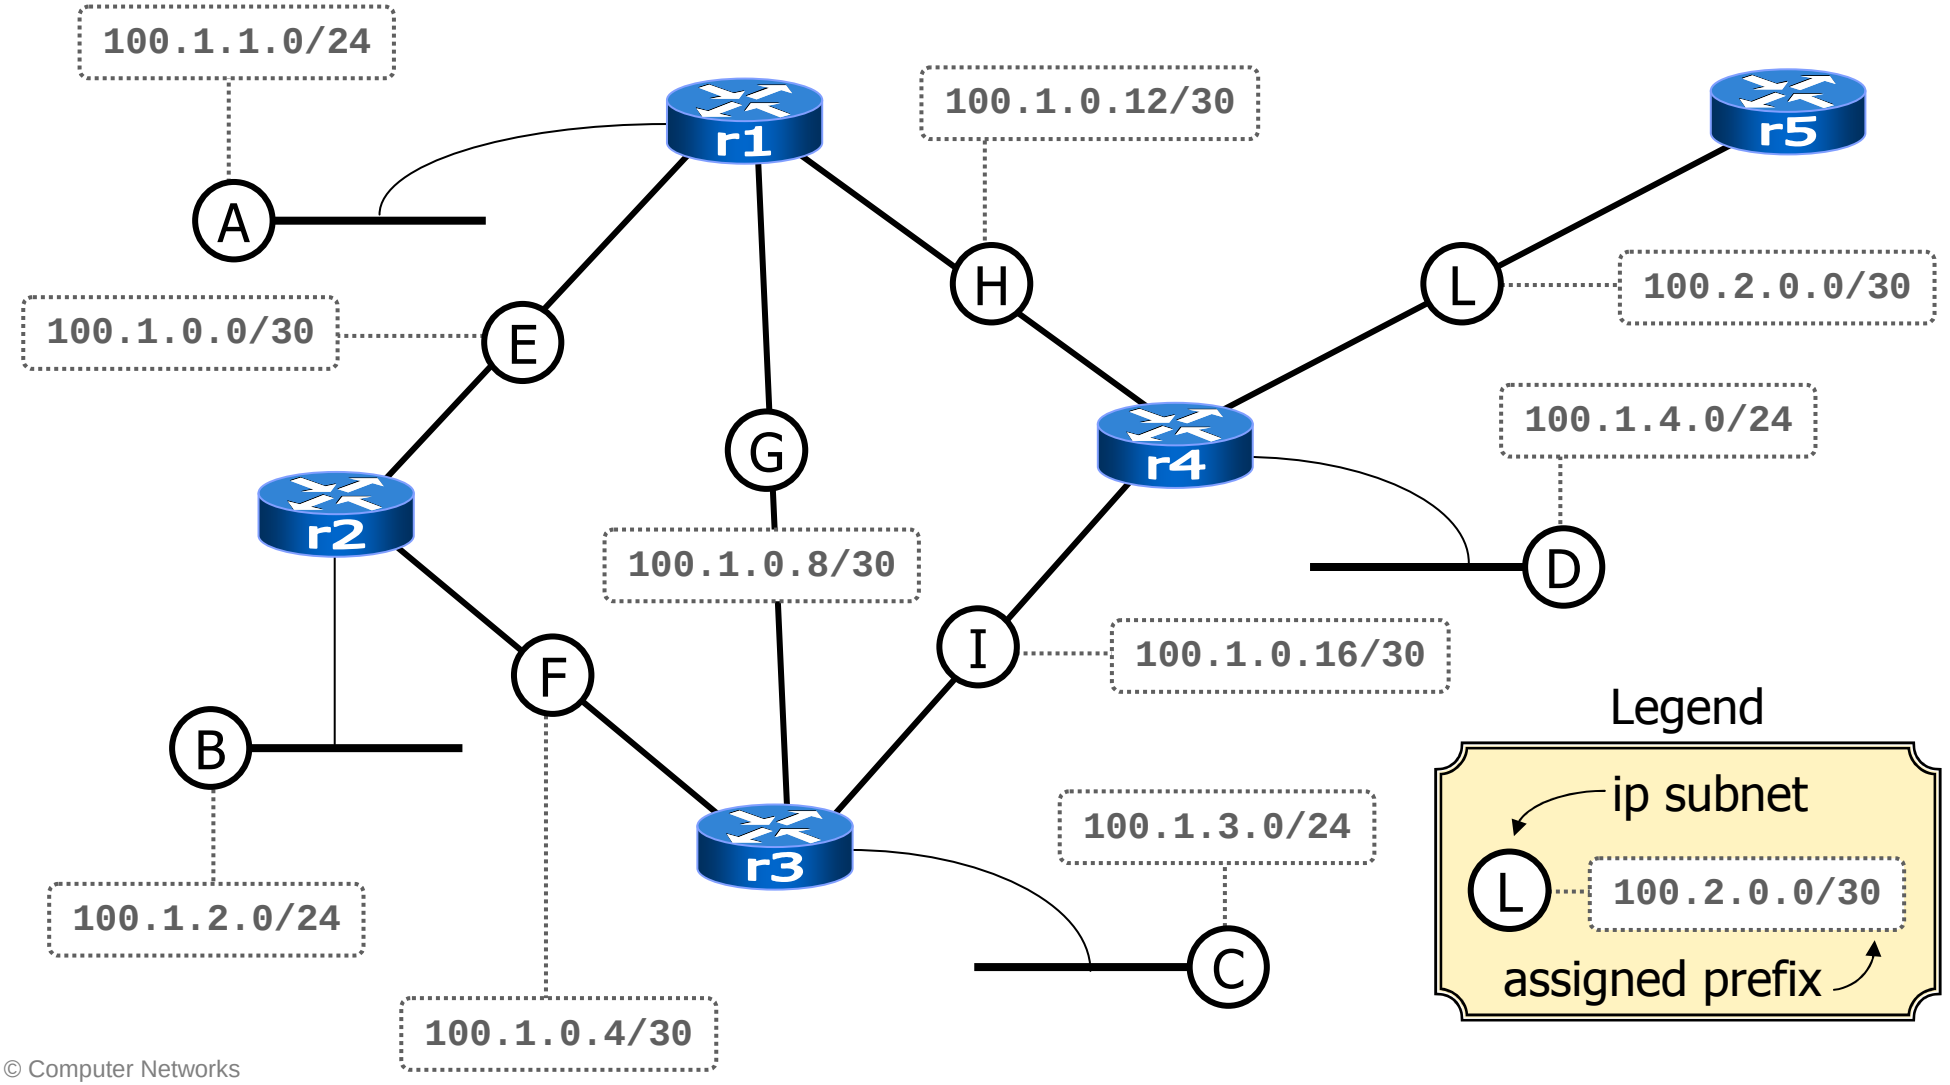
a small network connected to the Internet



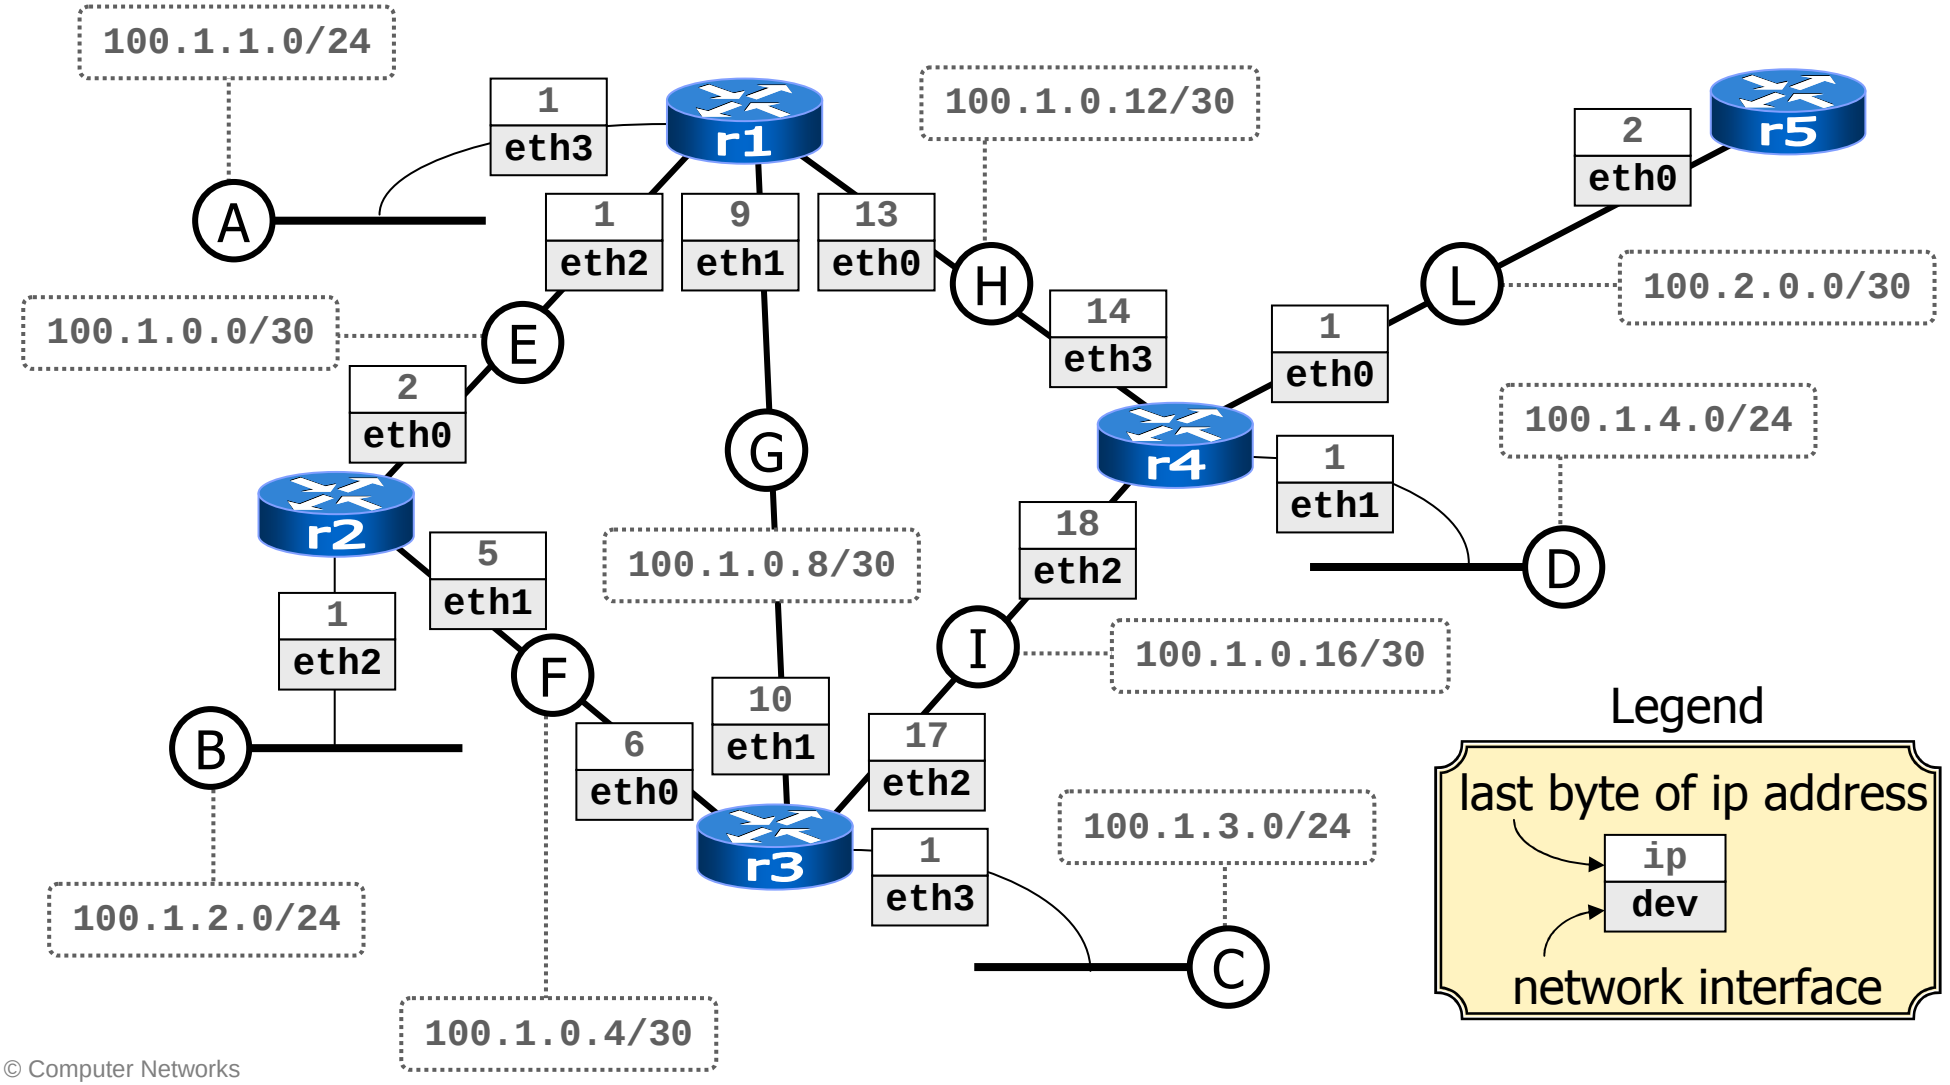
the involved ip subnets



assigning ip numbers to subnets



assigning ip numbers to interfaces



launching the lab script

- the lab configuration is such that
  - five virtual hosts are created and connected to the right collision domains (virtual hubs)
  - for each virtual host
    - network interfaces are automatically configured
    - configuration files **`/etc/zebra/daemons`**, **`/etc/zebra/zebra.conf`**, and **`/etc/zebra/ripd.conf`** are updated
  - the zebra routing daemon is not automatically started

checking connectivity

- towards a directly connected destination

r4

```
r4:~# ping 100.1.0.13

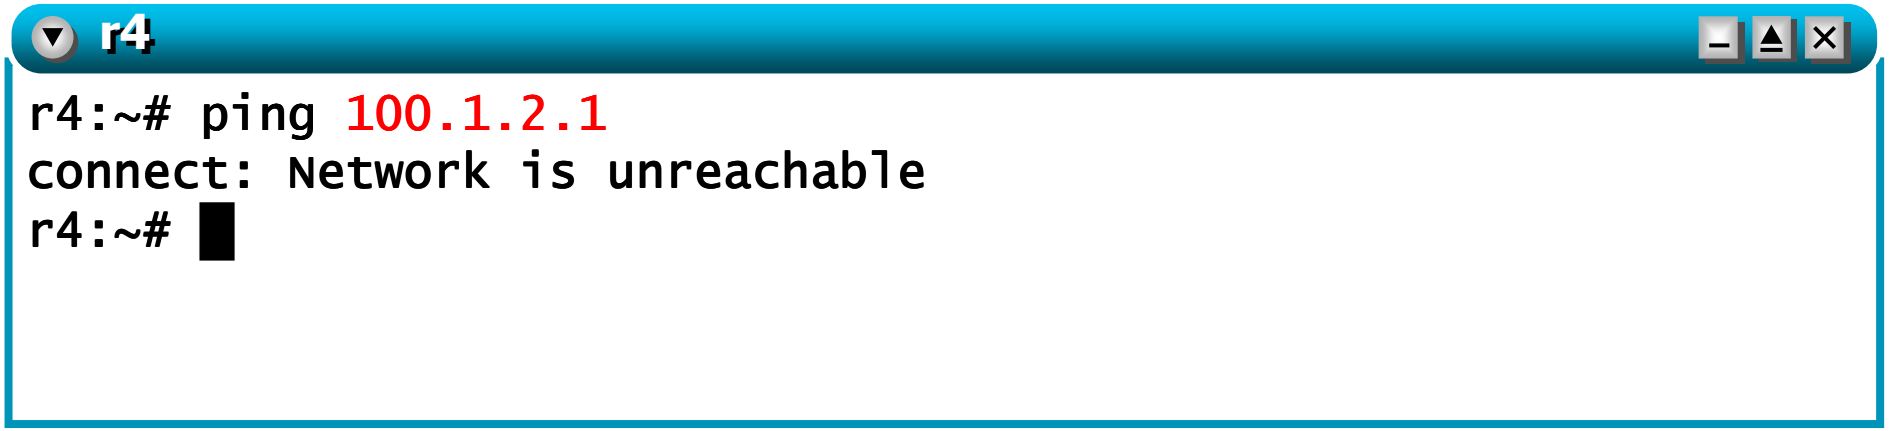
checking connectivity

- towards a remote destination



- what's going on?

examining the kernel routing table

r4

```
r4:~# route

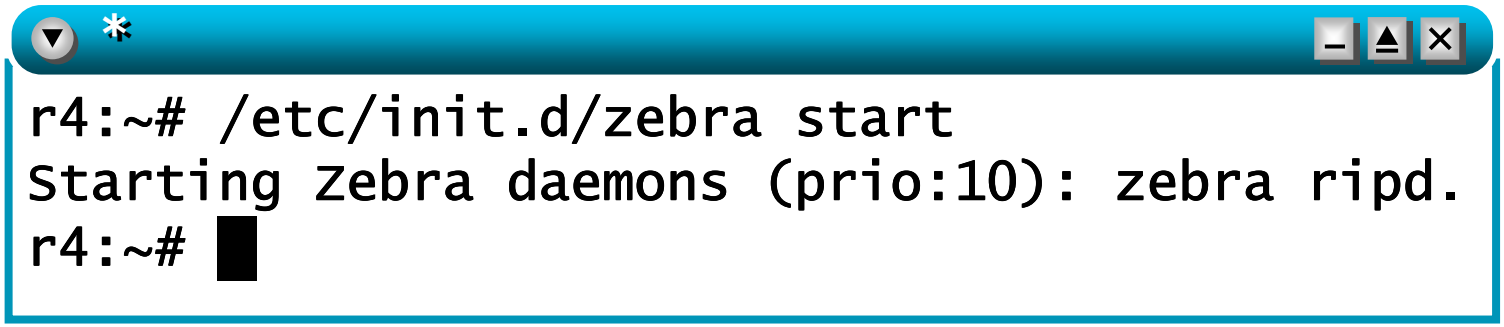
r4:~#
```

- since no routing daemon is currently running, only directly connected destinations are known to the router

starting the routing daemons

- on each router (but **`r5`**) issue the following command:



checking connectivity (again)

- towards a remote destination

r4

```
r4:~# ping 100.1.2.1

static routing

- our network is a stub network (i.e., it has just one connection to an external router, **r5**); hence, static routes are enough for connecting it to the internet
